

CLOCK CIRCUIT

The clock circuit consists of crystal Y1 and associated inverters and counters C3 and B3. Counters C3 and B3 count the crystal frequency down to the frequencies necessary for the Asteroids Deluxe™ game.

NOTE: The MPU in this game operates at a frequency of 1.5 MHz. Therefore the MPU chip must be the 6502A. The 6502's maximum frequency is 1 MHz and is not compatible with this game.

MPU CIRCUITRY

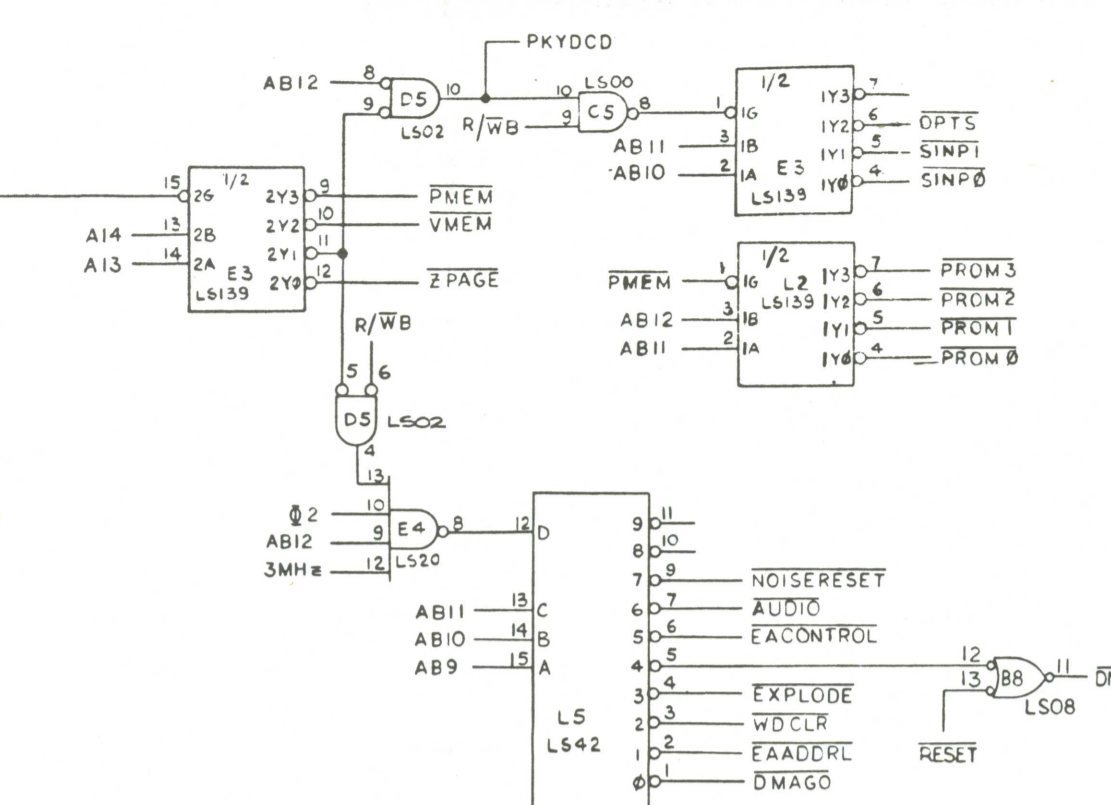

NOTE: DO NOT USE split pads on PCB for troubleshooting purposes.

NOTE: DO NOT USE split pads on PCB for troubleshooting purposes. If a 74LS244 is installed at location B1 and/or C1, the split pad for that location should be filled with solder. If a 74LS241 is used, the appropriate split pad should be open.

NOTE: Either a 74LS245 or an AM8304B may be used at location E2. Pin numbers not enclosed in parentheses are for 74LS245. Pin numbers in parentheses are for an AM8304B.

ADDRESS DECODING CIRCUITRY

The address decoder performs the function of turning on or enabling the appropriate circuitry at the critical time, so that information can be transferred back and forth between the game circuitry and the MPU. The memory map below is for the Asteroids Deluxe™ game.

If you are going to use the Automatic RAM/ROM Tester, please remember to remove MPU C3 and ground the WDOG DISABLE test point.

MEMORY MAP

Table with columns: HEXADECIMAL, ADDRESS (A15-A0), R/W, DATA (D7-D0), and FUNCTION. Lists memory locations from 03FF to 7800 and their corresponding hardware functions.

POWER RESET AND WATCHDOG COUNTER

During initial power-up, the delayed charging of capacitor C22 causes a preset of flip-flop D3 and a clear of counter D4. This results in holding RESET input to the MPU low. When the charge of C22 reaches about 1.5 VDC, preset and clear inputs are removed. Counter D4 counts to 128 at 3-KHz rate, and RESET is removed (goes high) from the input of the MPU. This allows the logic power input to the PCB to stabilize before allowing the MPU to begin its initialization routine.

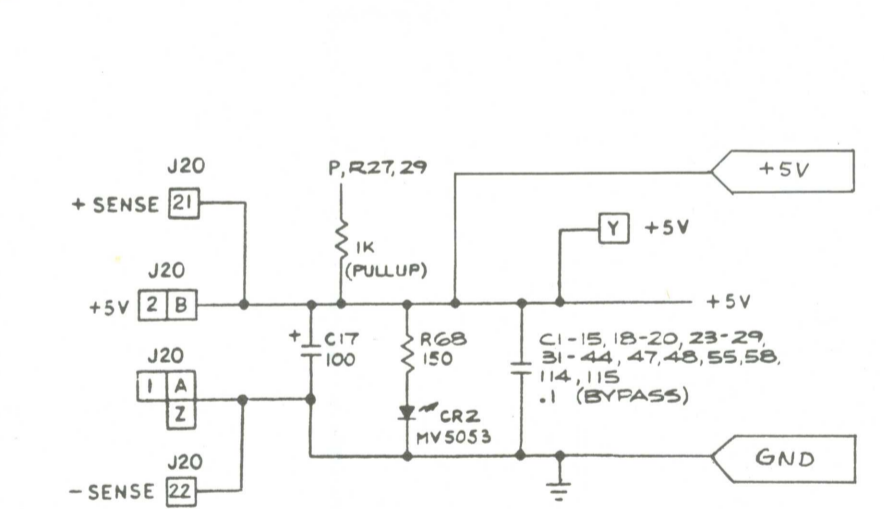

If the MPU program is operating properly, the MPU address decoding circuitry will output the WDCLR (Watchdog clear) signal at predetermined intervals. This serves to clear counter D4 before it counts up to the state that will create the RESET condition. If the MPU program strays from its intended sequence and does not output the WDCLR signal, counter D4 will count up to the RESET state and cause the MPU to return to its initialization routine.

NMI COUNTER

The NMI (non-maskable interrupt) counter causes an interrupt at the NMI input of the MPU every 4 msec. The interrupt is derived by dividing 3 KHz by a factor of 12 through counter C4. The interrupt occurs when pin 6 of inverter B4 goes low. During power-up, the NMI counter is disabled by RESET. During Self-Test, the NMI is disabled by TEST.

◀ Denotes a test point

POWER INPUT

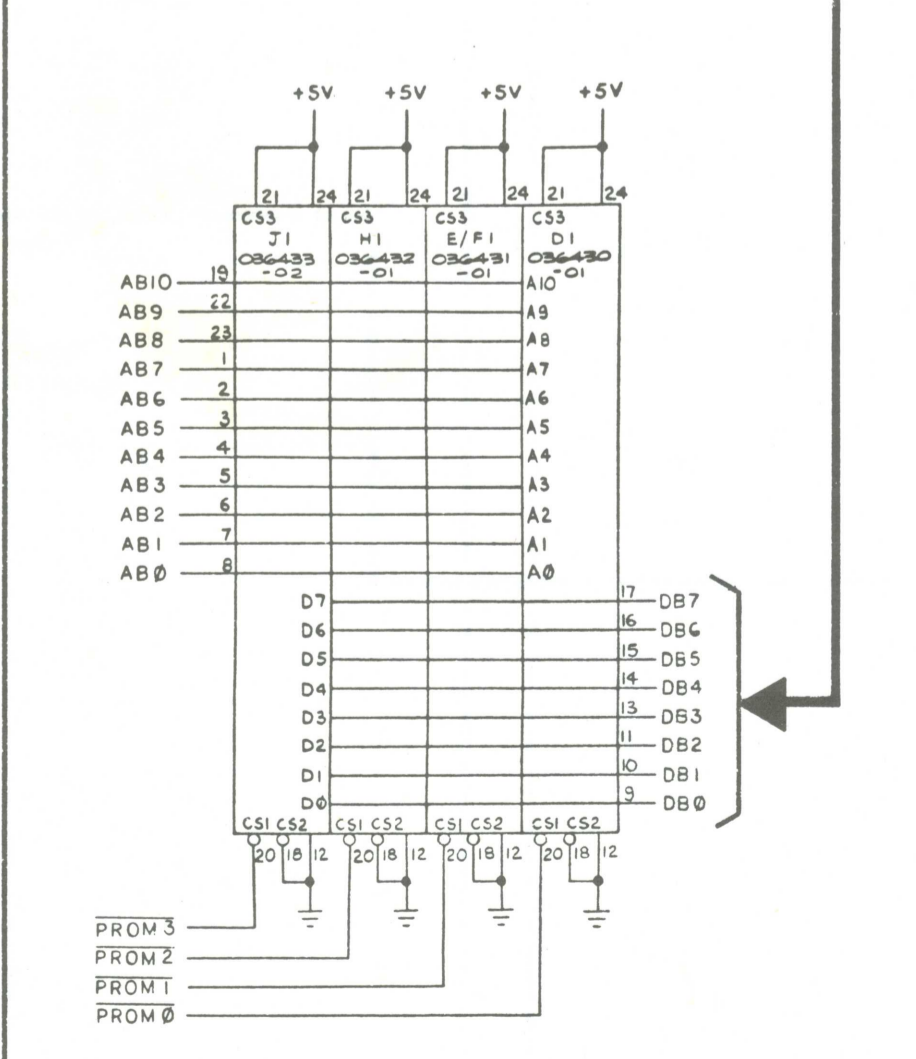

This circuitry consists of the PCB inputs and outputs for the +5 VDC logic power and 25 VAC input to the on-board regulators. The +5 VDC inputs and outputs are discussed on Sheet 1, Side A of this schematic set.

The 25 VAC inputs are received by two full wave rectifiers. Diodes CR9 and CR8 rectify the negative cycle of the input and the 7915 regulates the voltage at -15 VDC. Diodes CR9 and CR10 rectify the positive pulse of the 25 VAC input and the 7815 regulates the voltage at +15 VDC. The 7805 regulates at +12 VDC. The 7905 regulates an additional 5 VDC for the DACs. Zener diode CR12 supplies the +8.2 VDC for the sample and hold circuit. The +22V (unregulated) is used to power operational amplifiers P11 and L8 in the audio output.

ROM/PROM CIRCUITRY

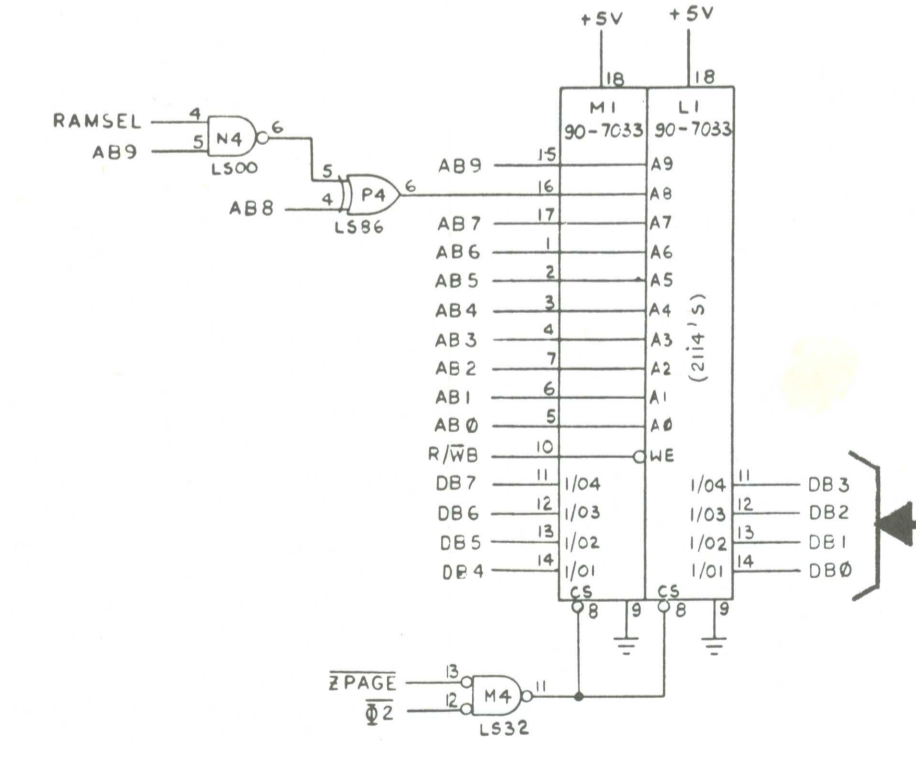

FROM SWITCH INPUTS SHEET 2, SIDE B

Program memory for the Asteroids Deluxe™ game is contained in three ROMs.

RAM CIRCUITRY

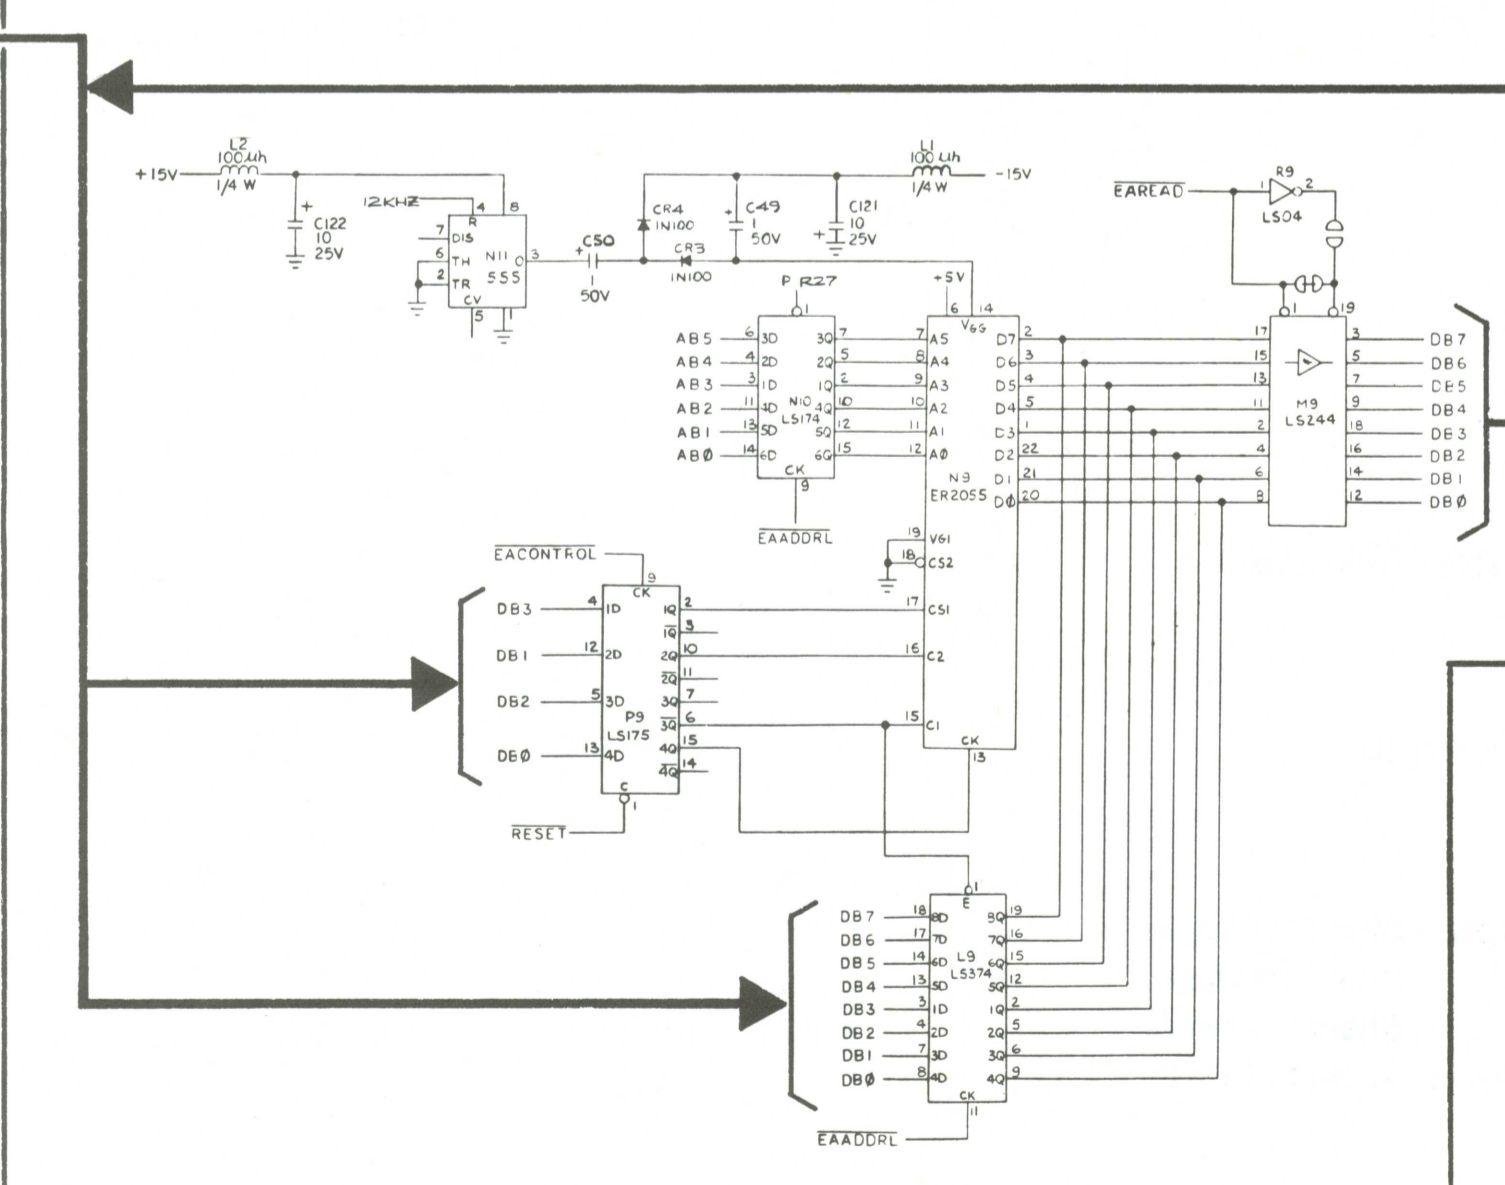

SHEET 2, SIDE B

The RAM is the temporary storage space for the MPU and is enabled when ZPAGE (Zero Page enable) is low. When R/WB (from the MPU) is low, the RAM stores the data byte input (DB0 thru DB7) at the location addressed by the MPU address bus (A0 thru A7). When R/WB is high, the MPU reads the stored data byte at the addressed location.

The signal RAMSEL, when low, has the effect of swapping pages 2 and 3 within the RAM. This allows greater programming flexibility.

HIGH SCORE CIRCUITRY

The High Score Memory circuit consists of an erasable reprogrammable ROM N9, latches L9, P9, N10 buffer M9, and timer N11.

N11 produces a 12KHz 0-15V squarewave. This signal when +15, forward biases diode CR4 and allows capacitor C50 to charge to +28V. When it's OV, CR4 is then cut-off and CR3 is forward biased which causes C49 to develop a charge. C49 charges to approximately +28V. This is the potential required for EAROM to operate.

The MPU addresses the EAROM (A0-A05) via latch N10, when EAADDRL goes high, and data is latched into the EAROM on DB0-DB7 through latch L9.

The function of the EAROM (read, write or erase) is determined by the MPU on data lines DB0-DB3. Latch D9 receives a high EACONTROL signal from the MPU address decoder and function data is passed to the EAROM.

Data in the EAROM is read by the MPU when the EAREAD is addressed by the MPU after a reset pulse or during self-test.
